Abstract: The interconnection and damping assignment passivity-based control (IDA-PBC) is well-known for regulating the behavior of nonlinear systems. In underactuated mechanical systems (UMSs), its application requires the satisfaction of matching conditions, which in many cases demands to solve partial differential equations (PDEs). Only recently, the IDA-PBC method has been extended to UMSs in implicit representation, where the system dynamics are described by a set of differential-algebraic equations. In some system classes, this implicit model allows to circumvent the PDE obstacle and to construct an output-feedback law. This paper discusses the design and real-system implementation of the total energy shaping IDA-PBC with an optimal local performance for a portal crane system in implicit port-Hamiltonian representation. The implicit controller is compared with the simplified (explicit) IDA-PBC, introduced by Xue and Zhiyong (2017), which also shapes the total energy and avoids PDEs.

Keywords: IDA-PBC, Port-Hamiltonian systems, Implicit systems, Passivity, Portal crane.

1. INTRODUCTION

The purpose of the interconnection and damping assignment passivity-based control (IDA-PBC) technique is to transform a nonlinear system into a closed-loop that takes a port-Hamiltonian (pH) structure with a desired target Hamiltonian. Its application requires to satisfy the so-called matching conditions. In underactuated mechanical systems (UMSs) the IDA-PBC method was first characterized using the explicit pH structure (Ortega et al., 2002), where shaping the energy usually requires the solution of two partial differential equations (PDEs): one for the kinetic energy and one for the potential energy. However, in general, solving these PDEs is not an easy task.

The IDA-PBC has already been tested on portal crane systems. For instance, Banavar et al. (2006) apply a potential energy-shaping IDA-PBC, while Singhal et al. (2006) employ the total energy-shaping IDA-PBC, with constant target inertia matrix. Later, on the basis of the PID-PBC, Donaire et al. (2015) present a method to shape the energy of a class of mechanical systems without solving PDEs and apply their results on a portal crane. Not long ago, Xue and Zhiyong (2017) implement in such a system the simplified IDA-PBC of Ryalat and Laila (2016) which reduces the potential energy PDE to a simple integral by selecting an adequate target inertia matrix. Above research uses the (simplified) planar model except for (Donaire et al., 2015) where the model is in 3-D. Moreover, all of these approaches use an explicit formulation.

The difference between an explicit and an implicit model relies on the considerations of physical constraints. Thus, complex systems can be modeled as simpler interconnected subsystems, where interconnections (constraints) are described by algebraic equations, forming a set of differential-algebraic equations (DAEs). In this context, Castaños et al. (2013) provide a complete geometric relation between the implicit and explicit port-Hamiltonian representations, concluding that the controller design or implementation is independent of its representation (implicit or explicit). Later, Macchelli (2014) extends the passivity-based control (PBC) theory applied to implicit systems on Dirac structures. Taking a closer look, Cieza and Reger (2019) extend the total energy shaping IDA-PBC technique to implicit UMSs. Their work gives a general method which is not restricted to holonomic systems and does not require a positive definite target inertia matrix. Besides, for some system classes, they can reduce the (energy shaping) PDEs to algebraic equations and devise an output-feedback law.

Until now, the Implicit IDA-PBC technique has remained in a theoretical and simulation framework with no physical implementation. Thus, the main contribution of this work is to work out the results of the implicit control algorithm on a constant rope-length portal crane system and compare these results with that of the simplified (explicit) IDA-PBC from Xue and Zhiyong (2017).

The paper is organized as follows. In Section 2, we briefly recall the implicit and explicit IDA-PBC approaches. Section 3 is devoted to analyzing the explicit planar (2-D) and implicit 3-D models of a portal crane. In Section 4, we apply both methods to the aforesaid system and present a
local linear performance assignment for the implicit controller. Section 5 presents the experimental results. Finally, we draw our conclusions in Section 6.

2. IMPLICIT AND EXPPLICIT IDA-PBC FOR UMS

Let us briefly summarize the general formulation of implicit IDA-PBC for UMSs introduced by Cieza and Reger (2019). Consider the implicit pH system

\[ \dot{\mathbf{x}} = 0 \begin{bmatrix} I_n & 0 \\ -I_n & 0 \end{bmatrix} \begin{bmatrix} \mathbf{H} \\ \mathbf{P} \end{bmatrix} + \begin{bmatrix} 0 \\ b(r) \end{bmatrix} \lambda + \begin{bmatrix} 0 \\ 0 \end{bmatrix} \mathbf{G}(r) \mathbf{u}, \]

\[ H(r, \rho) = \frac{1}{2} \rho^2 \mathcal{M}(r)^{-1} \rho + \mathcal{V}(r) \]

and the desired implicit pH system

\[ \dot{\mathbf{x}} = 0 \begin{bmatrix} \mathcal{J}(r) & -\mathcal{W}(r, \rho) \end{bmatrix} \begin{bmatrix} \mathbf{H}_d \\ \mathbf{P}_d \end{bmatrix} + \begin{bmatrix} 0 \\ b_d(r) \end{bmatrix} \lambda_d, \]

\[ \mathcal{H}(r, \rho) = \frac{1}{2} \rho^2 \mathcal{M}_d(r)^{-1} \rho + \mathcal{V}_d(r) \]

where \( r \in \mathbb{R}^n \) and \( \rho \in \mathbb{R}^n \) are implicit coordinates (position and its canonical momenta, respectively), \( u \in \mathbb{R}^n \) is the input, \( \mathcal{G} : \mathbb{R}^n \rightarrow \mathbb{R}^n \times m \) is the implicit input matrix, \( \mathcal{M}, \mathcal{M}_d : \mathbb{R}^n \rightarrow \mathbb{R}^n \times n \) are the (nominal and desired) nonsingular inertia matrices with \( \mathcal{M} \), \( \mathcal{H} : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R} \) are the Hamiltonians representing (nominal and desired) energy functions, (1b) and (2b) are kinematic constraints, and implicit variables \( \lambda, \lambda_d \in \mathbb{R}^n \) are related to the constraints forces \( b(r) \lambda, b_d(r) \lambda_d \) with \( b, b_d : \mathbb{R}^n \rightarrow \mathbb{R}^n \times n \). If (1) is holonomic (integrable constraints), then there exist a function \( \phi : \mathbb{R}^n \rightarrow \mathbb{R}^n \) such that \( \phi(r) = 0 \) (zero level set) and \( \partial_\mathcal{F} \phi(r) = b(r) \).

Definition 1. Let \( \mathcal{L}(r) = [\mathcal{G}(r) b(r)] \). System (1) with holonomic constraints is underactuated if rank \( S < n_h \); else it is fully actuated (Castaños and Gromov, 2016).

To avoid cumbersome notation we will omit the arguments of functions that have been defined previously.

Proposition 2. (Well posedness). Consider the implicit system (1). Then for all \( r \in \mathcal{X} := \{ r \in \mathbb{R}^n \mid \text{rank } \Delta = n_h \} \), \( \Delta = b^T M^{-1} b, \) the constrained state-space set \( \mathcal{X}_c := \{ (r, \rho) \in \mathcal{X} \times \mathbb{R}^n \mid b^T \partial_\mathcal{F} H = 0, \phi(r) = 0 \} \) is a regular manifold embedded in \( \mathbb{R}^n \times \mathbb{R}^n \), and (1) is a system of DAEs with unique solution for \( \lambda \) and differential index 1.

Let us define \( \Delta_d := b_d^T M_d^{-1} b_d \). Similarly, \( \lambda_d \) has a unique solution for all \( r \in \mathcal{X}_d := \{ r \in \mathbb{R}^n \mid \text{rank } \Delta_d = n_h \} \), which is obtained from the hidden constraint \( \lambda_d = \frac{1}{b_d^T \partial_\mathcal{F}_d H_d} \).

Proposition 3. (Implicit IDA-PBC). The implicit feedback \( u = u_d(r, \rho) \) with

\[ u_d(r, \rho) = S \left( \partial_\mathcal{H}^T \mathcal{J} \partial_\mathcal{F} H_d - \mathcal{W} \partial_\mathcal{F} H_d + \mathcal{J} b_d \lambda_d \right) \]

transforms the system (1) into (2) for all \( r \in \mathcal{X} \cap \mathcal{X}_d \), whenever the implicit matching conditions

1 We write \( \mathcal{P}^T \mathcal{P} = 0 \) or \( \mathcal{P}^T = \mathcal{P} \) for any vector or scalar function \( h(x) \). \( I_n \) denotes the identity matrix of size \( n \).
2 The constrained state space is the space of variables \( (r, \rho) \), while the configuration space (or manifold) is the space of coordinates \( r \).
3 We write the subscript \( \perp \) for any matrix \( F \) to represent its full rank left annihilator, i.e., \( F_\perp F = 0 \).
4 In what follows, \( \text{sym}(A) := A + A^T \), for any square matrix \( A \).
In Propositions 2–5 we have summarized the IDA-PBC methodology for implicit pH systems with holonomic constraints. Besides, if system (1) and (2) have no constraints, namely, (1b) and (2b), we can simply rewrite them as
\[
\frac{\dot{q}}{\dot{p}} = \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix} \begin{bmatrix} \partial_H^T H \\ \partial_p^T H \end{bmatrix} + \begin{bmatrix} 0 \\ G(q) \end{bmatrix} u, \quad \text{and} \quad (8)
\]
\[
\frac{\dot{q}}{\dot{p}} = \begin{bmatrix} 0 & J \\ -J^T & -W \end{bmatrix} \begin{bmatrix} \partial_q^T H \\ \partial_p^T H \end{bmatrix} u, \quad \text{and} \quad (9)
\]
respectively. Thus, the model is defined by means of the (explicit) generalized coordinates q and momenta p, where \( H(q,p) = \frac{1}{2} p^T M(q)^{-1} p + V(q) \), \( H_d(q,p) = \frac{1}{2} p^T M_d(q)^{-1} p + V_d(q) \) and \( M, M_d > 0 \). The following proposition recalls the standard IDA-PBC for UMSs as presented in (Donaire et al., 2016).

**Proposition 6.** (IDA-PBC). Feedback \( u = u_E(q,p) \) with
\[
u_E(q,p) = (G^T C)^{-1} G^T \left( \partial_q^T H - J^T \partial_q^T H_d - W \partial_p^T H_d \right) \quad (10)
\]
transforms system (8) into the desired system (9) whenever the kinetic and potential matching conditions
\[
G_\perp (\partial_q^T p^T M^{-1} p - J^T \partial_q^T p^T W - \partial_p^T H_d) = 0, \quad (11a)
\]
\[
G_\perp (\partial_q^T V - J^T \partial_q^T V_d) = 0 \quad (11b)
\]
are satisfied with \( J = M^{-1} M_d \) and \( W = \frac{1}{2} W_1(q,p) + G K \), for \( W_1 \) linear in \( p \). The closed loop system is stable in \((q^*,0)\) with \( q^* \in \{ q \mid G_\perp \partial_q^T V = 0 \} \) if \( q^* = \) arg min \( V_d \) is an isolated minimum, \( M_q \) is positive definite, \( \text{sym}(K_r) > 0 \), and \(^5\)
\[
\partial_p^T H_d W_1 \partial_p^T H_d = 0. \quad (11c)
\]
Moreover if \( y_E := G^T \partial_q^T H_d \) is a detectable output of (9), then the equilibrium is asymptotically stable.

Observe that the matching conditions (11) and control law (10) of the conventional (explicit) IDA-PBC for an UMS are a specific case \((S = G, q = r, p = \rho, M_d = M_d, J = J, W = W, \text{etc.})\) of the implicit IDA-PBC presented in Prop. 3.

### 3. PORTAL CRANE MODEL

This work focuses on the portal crane system shown in Fig. 1a, where the support mechanism (frame) is fastened to the floor. On the top, a set of girders and belts move the bridge of mass \( m_b \) and the trolley of mass \( m_t \) along the x-axis. The trolley, which is mounted under the bridge, is restricted to move in the \( y \)-direction. A basket hangs from a winch or rope drum, and thus it can move in the \( z \)-direction varying its length \( l \). A load can be attached to the basket in various ways and then transported with it. In the following, we refer to the basket and the additional weight as the payload of mass \( m_l \). The assumptions below are considered throughout this work.

A1. The rope mass is negligible.
A2. The payload is a point mass.
A3. The rope length \( l > 0 \) is fixed.
A4. The payload air friction is negligible.

\(^5\) Skew-symmetry of \( W_1 \) is a sufficient condition for (11c).

#### 3.1 3-D Implicit Model

The schematic view of the portal crane is given in Fig. 1b, where we describe the trolley position with \( r_t := \text{vec}(x_t, y_t) \), the payload relative position with \( r_p := \text{vec}(x_p, y_p, z_p) \), and the trolley external forces (actuators) on the \( x \)- and \( y \)-axis with \( \nu := \text{vec}(x_r, y_r) \). The selected coordinates lead to the holonomic constraint
\[
\phi := \frac{1}{2} (x_r^2 + y_r^2 + z_p^2 - l^2) = 0. \quad (12)
\]

To measure real positions, the system is equipped with encoders in \( x_t, y_t, l, \alpha \) and \( \beta \), where the geometric relation shown in Fig. 1c–1d results in
\[
x_p = l \sin \beta, \quad y_p = l \cos \beta \sin \alpha, \quad z_p = -l \cos \beta \cos \alpha. \quad (13)
\]

Following assumptions A1–A2, we may now calculate the kinetic and potential energy as
\[
\mathcal{K} = m_l \dot{x}_l^2 + \frac{1}{2} m_t \dot{y}_t^2 + \frac{1}{2} m_p l^2 (\dot{x}_r^2 + \dot{y}_r^2 + \dot{z}_p^2 + \dot{l}^2),
\]
\[
\mathcal{V} = m_p g r_z,
\]
ge where \( g_r \) is the gravity constant. From assumptions A3–A4 and coordinates \( r := \text{vec}(r_p, r_t) \), the Lagrange equations with external forces \( \mathcal{G} \) and constraints (12) gives
\[
\begin{bmatrix}
M_1 & M_2 \\
M_3 & M_3
\end{bmatrix}
\begin{bmatrix}
\ddot{r}_p \\
\dot{r}_t
\end{bmatrix}
+ \begin{bmatrix}
0 \\
\mathcal{G}_r \dot{r}_t
\end{bmatrix}
+ \begin{bmatrix}
\partial_{r_p}^T \mathcal{V} \\
\partial_{r_t}^T \mathcal{V}
\end{bmatrix}
= \begin{bmatrix}
\partial_{r_p}^T \phi \\
\partial_{r_t}^T \phi
\end{bmatrix} \dot{\lambda} + \begin{bmatrix}
0 \times 2 \\
I_2
\end{bmatrix} \nu,
\]
where \( M_2 = m_p \begin{bmatrix} I_2 \\
0_{1 \times 2}
\end{bmatrix}, \quad M_1 = m_p I_3, \quad M_3 = \text{diag}(m_t + m_b + m_p, m_l, m_t + m_b + m_p) \), and \( \mathcal{G}_r \) are the bridge-trolley frictions. By using partial feedback linearization (PFL) (Spong, 1994) with \( u = \dot{r}_t \) (trolley acceleration), it follows that
\[
\begin{bmatrix}
\ddot{r}_p \\
\ddot{r}_t
\end{bmatrix}
= \begin{bmatrix}
m_p^{-1} \partial_{r_p}^T \mathcal{V} \\
0
\end{bmatrix} + \begin{bmatrix}
m_p^{-1} \partial_{r_p}^T \dot{\phi} \\
0
\end{bmatrix} \dot{\lambda} + \begin{bmatrix}
- m_l^{-1} M_2 \\
0
\end{bmatrix} u, \quad (14a)
\]
\[
\nu = f_1 (r, \dot{r}, \dot{\lambda}) + f_2 (r) u, \quad (14b)
\]
for some functions \( f_1 \) and \( f_2 \). Now, we can rewrite (14a) as (1) with \( H(r, \rho) := \frac{1}{2} \rho^2 + g r_p, \quad b := \text{vec}(x_p, y_p, z_p, 0, 0), \quad G^T = \begin{bmatrix} -1 & 0 & 0 & 0 & 1 \end{bmatrix} \) and \( \lambda = \frac{1}{m_p} \). Note that \( M = I_5 \) which implies \( \dot{r} = \rho \).

\[^6\] We write vec \( (x_1, x_2, \ldots, x_n) \) as \( [x_1^T \ x_2^T \ \cdots \ x_n^T]^T \) for any scalars or column vectors \( x_1, x_2, \ldots, x_n \).
Our laboratory setup includes a PID + Feedforward trolley velocity loop as shown in Fig. 2. This inner loop with an additional integrator before \( \nu \) yields a system which can be approximated as (14a). Consequently, the integrator with PID + Feedforward is also an approximation of (14b), and it avoids the necessity to estimate the system masses (e.g., trolley, payload, bridge), inertias, and frictions.

\[
\begin{align*}
\text{Fig. 2. IDA-PBC block diagram}
\end{align*}
\]

### 3.2 Planar Explicit Model

To model the real crane of Fig. 1 in 2-D, the following assumption is required.

\[ A5. \text{ The angles } \beta \text{ and } \alpha \text{ are sufficiently small s.t. the axes } (x \text{ and } y) \text{ are approximately decoupled.} \]

The dynamics of this reduced system with PFL can be found in (Xue and Zhiyong, 2017) and is given by two systems of the form of (8), where \( H(q,p) = \frac{\gamma}{p}P - \bar{g} \cos q_1, G(q) = \text{vec}(-a \cos q_1, 1), a = 1/l, \) and \( q = \bar{g} = g_1/l. \) Besides, this first system has \( q = \text{vec}(q_1, q_2) = \text{vec}(\beta, x_1) \) and \( u = \ddot{x}_1, \) while the second on has \( q = \text{vec}(q_1, q_2) = \text{vec}(\alpha, y_1) \) and \( u = \ddot{y}_1. \) Similar to the 3-D model with PFL we have \( M = I_2 \) and \( \dot{q} = p. \)

### 4. IDA-PBC IN THE PORTAL CRANE

#### 4.1 State Feedback Implicit IDA-PBC

We now use Prop. 3 to synthesize controller \( u_t. \) Since our desired position is \( r^* = \text{vec}(0, 0, -l, x_c^e, y_c^e), \) we see that \( b^t = \text{vec}(0, 0, -l, 0, 0). \) Selecting \( C = 0_{4 \times 1}, \)

\[
S_L = \begin{bmatrix}
-z_p & 0 \\
0 & -z_p \\
0 & -z_p \\
0 & -z_p \\
0 & 0
\end{bmatrix}
\]

and

\[
S_L = \begin{bmatrix}
-\ddot{x}_1 & 0 \\
0 & \ddot{y}_1 \\
0 & \ddot{y}_1 \\
0 & \ddot{y}_1 \\
0 & 0
\end{bmatrix}
\]

we obtain \( Z_s = b^t. \) From (4c) and (6a) for arbitrary \( x_p, y_p \) and \( z_p, \) it follows that \( \mu^* = \frac{g}{P x_p} \) and

\[
A = \begin{bmatrix}
a_1 & e_1 & D_{-a_1} & -e_1 \\
e_1 & a_2 & -e_1 & D_{-a_2} \\
D_{-a_1} & -e_1 & d_1 & e_2 \\
D_{-a_2} & -e_1 & d_1 & e_2
\end{bmatrix}
\]

where \( a_i, d_i, e_i, \) and \( D \) are arbitrary constants s.t. \( A > 0. \) In the next step we choose \( SS = G, \) which clearly fulfills (6b) because \( G \) is constant. Then, we calculate \( Z \) and pick \( L_G = [1 0 1 0 1] \) obtaining that (6c) is satisfied for any \( D > 0. \) In the following, to simplify analysis, we set \( e_1 = 0 \) and \( W_1 = 0_{5 \times 5}. \) At this point we are able to calculate

\[
\psi = \begin{bmatrix}
-D(x^*_t - x_1) + x_p(D_{-a_1} + d_1) \\
-D(y^*_t - y_1) + y_p(D_{-a_2} + d_2)
\end{bmatrix}^2 \gamma_1
\]

where \( \gamma_1 = d, a_0 - D^2 + 2Da_1 - a_2. \) Finally, we select \( K_p = \text{diag}(K_{q_1}, K_{q_2}), K_u > 0, K_u = \text{diag}(K_{q_1}, K_{q_2}, 0), \) \( K_{q_1} > 0, \) and \( A > 0. \) Now, all elements of the control law (3) are on hand.

#### 4.2 Output Feedback Implicit IDA-PBC

If additionally, \( a_1 = 0, \) then \( b_1 = M_dM^{-1}b = 0 \) holds and Prop. 5 can be used selecting \( K_p > 0, \) sym.(\( \lambda \)) > 0 and \( K_u = \text{diag}(K_{q_1}, K_{q_2}), K_{q_1} > 0. \)

#### 4.3 Explicit IDA-PBC Control Law

Xue and Zhiyong (2017) applied the simplified IDA-PBC introduced by Ryu and Lai (2016) on the portal crane model of Section 3.2. However, their feedback law has the velocity \( \dot{q}_p \) in the denominator, and thus, it is not well-defined for all \( (q, p) \in \mathcal{E} = \{ (q, p) \mid \dot{q}_p = 0 \}. \) Additional inspection shows that the kinetic matching condition is also not satisfied for all \( (q, p) \in \mathcal{E}. \) To avoid the aforementioned problems, we redesign the controller searching for new \( M_d \) and \( V_d. \)

Let \( G_{\perp} = [1 \cos q_1, W_1 = \begin{bmatrix}
0 & -s \\
s & 0
\end{bmatrix}, s = s_1(q_1), \eta_1 + s_2(q_1) \eta_2, M_d = \begin{bmatrix}
m_1 & m_2 & m_3 & m_4 & m_5 \n_m & m_7 & m_8 & m_9 & m_{10}
\end{bmatrix}, \) and \( \eta := \partial_p^2 H_d = \text{vec}(\eta_1, \eta_2), \) then (11a) can be reduced to

\[
K_1 \eta \partial_q^2 (M_d) \eta + 2 G_{\perp} \begin{bmatrix}
0 & -s \\
s & 0
\end{bmatrix} \eta = 0,
\]

where \( K_1 = m_1(q_1) + a m_2(q_1) \cos q_1. \) Equation (15) has a solution for arbitrary \( \eta_1 \) and \( \eta_2 \) if and only if \( s_2(q_1) \eta_1 = 0, \) \( K_1 \partial_q (m_1) + 2a s_1(q_1) \cos q_1 = 0, \) and \( (16a) K_1 \partial_q (m_2) - s_1(q_1) = 0. \)

We can simplify the potential energy PDE (11b) to a simple integral by selecting \( m_2(q_1) = -a m_3 \cos q_1. \) Now we can solve (16), obtaining \( s_1 = K_1 a m_3 \sin(q_1) \) and \( m_1 = a^2 m_3 \cos(q_1)^2 + c_1 \) for some constant \( c_1. \) Therefore, \( M_d = \begin{bmatrix}
a^2 m_3 \cos(q_1)^2 + c_1 & -a m_3 \cos q_1 \\
-a m_3 \cos q_1 & m_3
\end{bmatrix}, \)

\[
V_d = -\dot{q}_p \cos q_1 \cos q_1 + \mathcal{T}(q_2),
\]

with \( \mathcal{T} \) being an arbitrary function. Let \( \mathcal{T} := \frac{1}{2} K_p (q_2 - q_2^*)^2, \) then it is straightforward to proof that \( M_d > 0 \) and \( q^* = (0, q_2^*) \) is a strict local minimum of \( V_d \) if \( K_p > 0, c_1 > 0, \) and \( m_3 > 0. \) Finally, choosing \( K_s > 0, \) we see that the (explicit) IDA-PBC controller (10) is reduced to

\[
u_E(q, \dot{q}) = \begin{bmatrix}
m_3 \sin(q_1) \\
(\dot{q}_2 \dot{q}_1 a^2 \cos q_1 + a \dot{q}_1^2 + \dot{q}_2 \cos q_1)
\end{bmatrix}_c
\]

\[
+ K_p m_3 (q_2^* - q_2) - K_v q_2
\]

Clearly, the previous controller is well defined for any \( q_2 \) and is independent of any mass.

#### 4.4 Local Linear Performance

Using Proposition 5 of (Cieza and Reger, 2019) we can reduce the implicit (holonomic) system (14a) in the

\[ \text{7} \] The coordinate reduction eliminates the constraint \( b^T \partial_q \mathcal{H} = 0 \) and constraint forces \( b \lambda. \)
form of (1) to an explicit pH representation of the form of (8), where $q = \text{vec}(\beta, \alpha, x_t, y_t)$, $M = (\partial_q^T h)M(\partial_q h)$, $\rho = \dot{r} = (\partial_q^T h)M^{-1} p$, $G = (\partial_q^T h)G$, $V = V(h(q))$, and the geometric relation $r = h(q)$ is defined by (13). Note that the implicit inertia matrix $M$ is constant, while the explicit one, $\tilde{M}$, is not. Let $x := \text{vec}(q, p)$. The linearization of the portal-crane system with controller (3) about the point $x = x^* := \text{vec}(\bar{\beta}, \bar{\alpha}, \bar{x}_t, \bar{y}_t, 0, 0, 0, 0)$ is

$$\dot{x} = (A_r + B_r \tilde{K}_I)x,$$

where $\tilde{x} = x - x^*$, $u_I(q, p) = u_I(h(q), (\partial_q^T h)M^{-1} p)$.

$$A_r = \begin{bmatrix} 0 & I_4 & \frac{\partial^2 H}{\partial x^2}x=x=0 \end{bmatrix}, \quad B_r = \begin{bmatrix} 0_{4 \times 2} \end{bmatrix} G(0),$$

$$K_I = \partial_x u_I \big|_{x=0} = \begin{bmatrix} k_{11} & 0 & k_{12} & 0 & k_{13} & 0 & k_{14} & 0 \ 0 & k_{21} & 0 & k_{22} & 0 & k_{23} & 0 & k_{24} \end{bmatrix},$$

$$k_{i1} = \frac{K_{r1}(D-a_i + d_i)}{l_{i1}} + \frac{a_i g_c}{D} - g_r, \quad k_{i2} = \frac{-DK_{r1}}{l_{i1}},$$

$$k_{i3} = \frac{K_{r0}(D-a_i + d_i)}{l_{i1}}, \quad k_{i4} = \frac{K_{r0}D}{l_{i1}}.$$ 

Since the pair $(A_r, B_r)$ is controllable for any $l > 0$, we can easily set an LQR local optimal performance to our controller (3) by solving $a_i$, $d_i$, $D$, $K_r$ and $K_u$ from $-K_{rqr} = K_I$, where the LQR feedback is $u_{lqr} = -K_{lqr} \tilde{x}$. Similarly, linearization of the 2-D model (see Section 3.2) with $x := \text{vec}(q_1, q_2, q_1, q_2)$ and the explicit IDA-PBC controller (19) yields

$$K_E = \partial_x u_E \big|_{x=0} = \begin{bmatrix} a g m_3 c_1 & -K_p m_3 \ 0 & -K_p m_3 \end{bmatrix}.$$ 

In comparison, the presence of 0 in the matrix $K_E$ prevents to set an arbitrary LQR local performance, which is a disadvantage of (19) with respect to (3).

5. EXPERIMENTAL RESULTS

Figures 3–5 show experimental step responses with initial conditions $x_t = y_t = \bar{\beta} = \bar{\alpha} = \bar{x}_t = \bar{y}_t = \bar{\beta} = \bar{\alpha} = 0$ under five control actions: two implicit full state-feedback IDA-PBC ($u_{l1}$ and $u_{l2}$), an implicit output-feedback IDA-PBC ($u_{e}$), an explicit full state-feedback IDA-PBC ($u_{g}$), and an LQR ($u_{lqr}$). To compare the $u_{qr}$ and the implicit law $u_I$ we assign the same local performance, i.e., $-K_{qr} = K_I$, and rename $u_I$ as $u_I$. Here $u_{lqr}$ is obtained from $A_r$, $B_r$, $Q_{lqr}$ is $\text{diag}(400, 400, 100, 100, 10, 10, 1, 1)$, and $R_{lqr} = I_2$. Since the explicit controller $u_E$ does not allow an arbitrary local optimal performance or pole assignment, see Section 4.4, we choose the parameters of $u_I$ s.t. $K_E = [k_{11} k_{21} k_{12} k_{13} k_{41}]$, and call it $u_{l2}$. The parameters of the IDA-PBC controllers are shown in Table 1, where $g_r = 9.81 \text{m/s}^2$, $l = 1 \text{m}$, $m_p = 4.975 \text{kg}$.

First, we observe that all controllers achieve asymptotic stability of the desired position. Besides, since the crane angles $\beta$ and $\alpha$ are rather small ($-10^\circ < \alpha, \beta < 10^\circ$), we have a very similar behavior for the pairs $u_{l1} - u_{lqr}$ and $u_{e} - u_{l2}$. Clearly, the optimal local performance allows a faster settling time and smaller overshoot of $u_{l1}$ and $u_{lqr}$ with respect to $u_E$. The output-feedback law requires the additional parameter restriction $a_i = D$, so it yields the slowest settling time, but avoids any velocity measurement. Finally, note that the implementation of the implicit IDA-PBC does not depend on the linearization or

\[\text{Fig. 3. Crane response: signals } x_t \text{ and } y_t.\]

\[\text{Fig. 4. Crane response: signals } \beta \text{ and } \alpha.\]
assumption A5. Consequently, it may allow a larger region of attraction (compared with the local u_{lqr} and u_E).

6. CONCLUSION

Explicit and implicit IDA-PBC approaches are designed and implemented successfully on an experimental portal crane system. Both methods shape the total energy without solving PDEs. The simplified (explicit) IDA-PBC uses a 2-D model, which is obtained under small angle assumption (relative position of the payload w.r.t. the trolley). In contrasts, the implicit IDA-PBC uses a 3-D model, avoiding the previous requirement.

On the other hand, we found a significant implementation flaw in the simplified IDA-PBC of Xue and Zhiyong (2017) and solve it by picking a new target Hamiltonian. The application of this method in the portal crane with a 3-D model is not as straightforward as the one modeled in 2-D. Therefore, we restrict this method to 2-D and apply the feedback in each axis ($x$ and $y$) as if they were decoupled.

Finally, we compare five control actions: an LQR, an implicit state-feedback IDA-PBC tuned to have the same local behavior as the LQR, a simplified (explicit) IDA-PBC, an implicit state-feedback IDA-PBC tuned to behave locally as the explicit one, and an output-feedback implicit IDA-PBC. The results give favour to the implicit IDA-PBC instead of the simplified explicit one.
